## Dynamic Programming Optimizations

By [indy256](#), 2 years ago,  

Several recent problems on Codeforces concerned dynamic programming optimization techniques.

The following table summarizes methods known to me.

Name	Original Recurrence	Sufficient Condition of Applicability	Original Complexity	Optimized Complexity	Links	User	Rating	
				1		tourist	3374	
				2		Petr	3003	
Convex Hull Optimization1	$dp[i] = \min_{j < i} \{dp[j] + b[j] \star a[i]\}$	$b[j] \geq b[j + 1]$ optionally $a[i] \leq a[i + 1]$	$O(n^2)$	3		vepifanov	2963	
				4	p1	Endagorion	2956	
				5		rng_58	2941	
Convex Hull Optimization2	$dp[i][j] = \min_{k < j} \{dp[i - 1][k] + b[k] \star a[j]\}$	$b[k] \geq b[k + 1]$ optionally $a[j] \leq a[j + 1]$	$O(kn^2)$	6	1	subscriber	2895	
				7		WJMZBMR	2853	
				8		scott_wu	2841	
Divide and Conquer Optimization	$dp[i][j] = \min_{k < j} \{dp[i - 1][k] + C[k][j]\}$	$A[i][j] \leq A[i][j + 1]$	$O(kn^2)$	9		TooSimple	2826	
				10	p1	qwerty787788	2824	
					<a href="#">Countries</a>   <a href="#">Cities</a>   <a href="#">Organizations</a> <a href="#">View all →</a>			
Knuth Optimization	$dp[i][j] = \min_{i < k < j} \{dp[i][k] + dp[k][j]\} + C[i][j]$	$A[i, j - 1] \leq A[i, j] \leq A[i + 1, j]$	$O(n^3)$	$O(n^2)$	12	Top contributors		
					#	p1	User	Contrib

Notes:

- $A[i][j]$  — the smallest  $k$  that gives optimal answer, for example in  $dp[i][j] = dp[i-1][k] + C[k][j]$
- $C[i][j]$  — some given cost function
- We can generalize a bit in the following way:  $dp[i] = \min_{j < i} \{F[j] + b[j] * a[i]\}$ , where  $F[j]$  is computed from  $dp[j]$  in constant time.
- It looks like **Convex Hull Optimization2** is a special case of **Divide and Conquer Optimization**.
- It is claimed (in the references) that **Knuth Optimization** is applicable if  $C[i][j]$  satisfies the following 2 conditions:
  - **quadrangle inequality**:  $C[a][c] + C[b][d] \leq C[a][d] + C[b][c]$ ,  $a \leq b \leq c \leq d$
  - **monotonicity**:  $C[b][c] \leq C[a][d]$ ,  $a \leq b \leq c \leq d$
- It is claimed (in the references) that the recurrence  $dp[j] = \min_{i < j} \{dp[i] + C[i][j]\}$  can be solved in  $O(n \log n)$  (and even  $O(n)$ ) if  $C[i][j]$  satisfies **quadrangle inequality**. **WJMZBMR** described how to solve some case of this problem.

Open questions:

1. Are there any other optimization techniques?
2. What is the sufficient condition of applying **Divide and Conquer Optimization** in terms of function  $C[i][j]$ ? Answered

Here is another way to optimize some 1D1D dynamic programming problem that I know.

Suppose that the old choice will only be worse compare to the new choice(it is quite common in such kind of problems).

Then suppose at current time we are deal with  $dp_i$ , and we have some choice  $a_0 < a_1 < a_2, \dots, a_{k-1} < a_k$ . then we know at current time  $a_i$  should be better than  $a_{i+1}$ . Otherwise it will never be better than  $a_{i+1}$ , so it is useless.

WJMZBMR

we can use a deque to store all the  $a_i$ .

And Also Let us denote  $D(a, b)$  as the smallest  $i$  such that choice  $b$  will be better than  $a$ .

If  $D(a_i, a_{i+1}) > D(a_{i+1}, a_{i+2})$ , we can find  $a_{i+1}$  is also useless because when it overpass  $a_i$ , it is already overpass by  $a_{i+2}$ .

So we also let  $D(a_i, a_{i+1}) < D(a_{i+1}, a_{i+2})$ . then we can find the overpass will only happen at the front of the deque.

So we can maintain this deque quickly, and if we can solve  $D(a, b)$  in  $O(1)$ , it can run in  $O(n)$ .

For question 2: The sufficient condition is:  $C[a][d] + C[b][c] \geq C[a][c] + C[b][d]$  where  $a < b < c < d$ .

Is it quadrangle inequalities?

$\forall i, j, w[i, j] + w[i+1, j+1] \leq w[i+1, j] + w[i, j+1]$ , and are these two inequalities equivalent except the  $\geq$  &  $\leq$ ?

hogloid

The problem mentioned in the article (Breaking Strings) is "Optimal Binary Search Tree Problem", traditional one.

It can be solved by simple DP in  $O(N^3)$ , by using Knuth's optimization, in  $O(N^2)$ . But it still can be solved in  $O(N \log N)$  — <http://poj.org/problem?id=1738> (same problem but bigger testcases) (I don't know how to solve it. I hear the algorithm uses meld-able heap)

Is this the best complexity for this problem? Can't we do any better? Can't we somehow turn the  $\log L$  needed into a constant?

→ [Reply](#)

3 weeks ago, # ^ |

▲ 0 ▼

We can, using that

$$\text{opt}[i-1][j] \leq \text{opt}[i][j] \leq \text{opt}[i][j+1]$$

micklepru

Key thing is to see that  $\text{opt}$  function is monotone for both arguments. With that observation, we don't need to use binary search.

Check out my submission.

Can matrix chain multiplication problem b also optimized by knuth optimization? If not, dn why?

→ [Reply](#)

12 months ago, # ^ |

▲ +3 ▼

Quote from the first of the references above:

*The monotonicity property for the division points does not hold for the matrix multiplication chain problem...*

indy256

*Consider the matrices  $M_1, M_2, M_3, M_4$  with dimensions  $2 \times 3, 3 \times 2, 2 \times 10$ , and  $10 \times 1$ , respectively. As can be easily verified, the proper order to compute  $M_1 M_2 M_3$  is to parenthesize it as  $(M_1 M_2) M_3$ , while the optimal computation of  $M_1 M_2 M_3 M_4$  corresponds to  $M_1 (M_2 (M_3 M_4))$ .*

The second reference gives  $O(n^2)$  dynamic programming solution, based on some properties of the matrix chain multiplication problem.

There is also an  $O(n * \log n)$  algorithm by Hu and Shing.

Can this problem be solved using convex hull optimization?

Can this problem be solved using convex hull optimization?

You are given a sequence  $A$  of  $N$  positive integers. Let's define "value of a splitting" the sequence to  $K$  blocks as a sum of maximums in each of  $K$  blocks. For given  $K$  find the minimal possible value of splittings.

EXM\_KG

$$N \leq 10^5$$

$$K \leq 100$$

I don't think so, but I guess it can be solved by Divide And Conquer optimization.

→ [Reply](#)

3 months ago, # |

▲ 0 ▼

Could you elaborate a little me more in the "Convex Hull Optimization2" and other sections for the clearer notations.

For example, You have "k" — a constant in  $O(kn^2)$ . So the first dimension is of the length  $K$  and the second dimension is of the length  $N$ ?

I think it would be clearer if you can write  $dp[n]$ ,  $dp[k][n]$  ... instead of  $dp[i]$ ,  $dp[i][j]$ .

Best regards,
