In this problem you are about to deal with N creatures entering the city. Each creature has its own power and there are 2 entrances to the city.

Creatures enter the city one by one in the following manner:

While there are creatures outside the city:

One of creatures from outside the city decides to enter it. It picks one of its two entrances to do that and go there.

You see that these can produce different arrangements of creatures at the entrances. We call an arrangement a good arrangement if and only if **at any time**, the sum of powers of creatures standing in the first entrance is not greater than the sum of powers of creatures standing in the second entrance. Any other arrangement is bad.

Your task here is to count the number of good arrangements. Knowing this and the sum of powers of all creatures is enough to provide a correct output.

First observation that we can make is to notice that N is small enough to iterate over all permutations of creatures. For each such permutation we can consider at most 2^N arrangements of creatures to the entrances while taking into result just the good ones. It is important to see that we do not have and should not consider any arrangement which is not good. So when we are about to place a creature at the first entrance, we check if the produced arrangement is good and if it is not, we do not extend it any further.

Time complexity

The exact time complexity depends on values of powers of individual creatures. It is definitely $O(N! \cdot 2^N)$ which is about $2 \cdot 10^8$ operations, but for a fixed permutation of creatures, not extending bad arrangements further, allows us to avoid checking many unnecessary arrangements. For example, for a fixed permutation of creatures, placing the first creature in the permutation which has a positive power at the first entrance, will produce a bad arrangement so we will not consider any such arrangement. To sum up, this method will easily pass all testcases in time.

My solution is available [here](#).

```
1. #include <bits/stdc++.h>
2. using namespace std;
3.
4. int arr[13], n, ans = 0, entrance1, entrance2;
5.
6. void solve(int num) {
7.     if(num == n){
8.         ans++;
9.         return;
10.    }
11.
12.    if (entrance1 + arr[num] <= entrance2) {
13.        entrance1 += arr[num];
14.        solve(num + 1);
15.        entrance1 -= arr[num];
16.    }
17.    entrance2 += arr[num];
18.    solve(num + 1);
19.    entrance2 -= arr[num];
20. }
21.
22. int main() {
23.     scanf("%d",&n);
24.     int sum = 0;
25.     for(int i=0; i<n; i++) {
26.         scanf("%d",&arr[i]);
27.         sum += arr[i];
28.     }
29.     sort(arr, arr+n);
30.     do{
31.         entrance1=0; entrance2=0;
32.         solve(0);
33.     }while(next_permutation(arr,arr+n));
34.     printf("%d %d\n",ans, sum);
35.     if (ans>sum)
36.         printf("We will win!\n");
37.     else
38.         printf("Got no way out!\n");
39.     return 0;
40. }
